Course Description

This course provides an overview of optimizing commercial fenestration with thermal barriers and high-performance glazing components in aluminum windows, storefronts, and curtain-wall framing in the building envelope.

Learning Objectives

After completing this course, you should be able to:

1. Discuss energy efficiency in commercial buildings and initiatives to reduce energy consumption to save costs while also supporting occupant health.
2. Investigate performance-, health-, and comfort-related topics in aluminum fenestration systems, including material sustainability, thermal and structural performance, noise abatement, and condensation resistance.
3. Evaluate the performance of aluminum window, storefront, and curtain-wall fenestration systems in the building envelope through the application of structural thermal barriers and high-performance glazing.
4. Analyze a range of fenestration product types, measured performance outcomes, energy savings, and LEED and Passive House contribution through observing multiple case studies.

Fenestration Energy Efficiency and Its Terminology

Performance in Fenestration Systems

- Government, nongovernmental organizations (NGOs), policymakers
- Mega-trends: green awareness, sustainability, carbon footprints, zero-net energy (ZNE), Title 24
- EPA, DOE, USGBC, ASHRAE, NFRC, IECC, LCA

Before LEED and other specialty green certification and rating programs, there was no universal method of measuring construction practices and material impacts, so there were no social, environmental, and energy use standards. There was not yet any way to accurately or completely describe community benefits and sustainability impacts using a number.

Governments and nongovernmental organizations throughout the world are looking for more ways to be sustainable, resilient, and promote environmental conservation. Modern buildings are designed to reduce the overall impact of the built environment on human health and the natural environment.

Traditionally constructed buildings account for a large amount of energy consumption through the use of fossil fuels and 24 percent of global carbon dioxide emissions.

Performance in Fenestration Systems

- **Fenestration (architecture)** refers to the design, construction, or presence of openings in a building.
- **Fenestration** includes windows, doors, louvres, vents, wall panels, skylights, storefronts, curtain walls, and slope glazed systems.

Photo:
Sangren Hall
Western Michigan University
Kalamazoo, Michigan
LEED BD+C: New Construction v3 – LEED 2009

Sangren Hall is a LEED Gold, 230,000-square-foot facility completed in 2012 that contains the College of Education and Human Development and the Department of Sociology, located in the heart of the Western Michigan University campus.

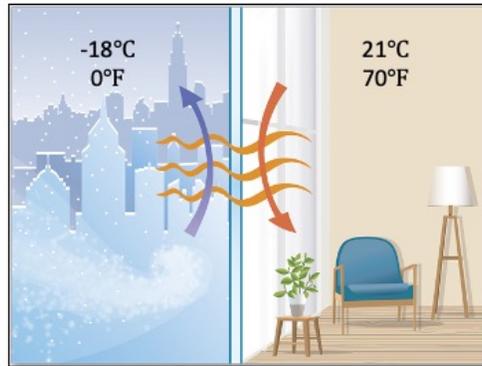

The large windows allow daylight to penetrate into the interior office spaces on every floor of the university building, saving electricity and providing a pleasant atmosphere for occupants.

Daylight must be properly integrated with the electric lighting system for its energy-savings potential to be realized. Sangren Hall employs occupant sensors to detect when a room is not being used, turning off lights or making adjustments to further reduce electricity use. This photo shows the exterior curtain wall that permits daylight to penetrate the space, allowing sufficient natural light to illuminate the interior during the peak hours that the school will be occupied.

Performance in Fenestration Systems

U-Factor: The rate of heat loss is indicated in terms of the U-factor (U-value) of a window assembly. The lower the U-factor, the greater a window's resistance to heat flow and the better its insulating properties.

Condensation Resistance Factor (CRF): CRF numbers for windows range from 30 to 80; the higher the number, the better the window is at resisting condensation.

U-factor measures the rate of heat transfer and tells you how well the window insulates. U-factor values are measured in $\text{Btu}/\text{h}\cdot\text{ft}^2\cdot^\circ\text{F}$. The lower the U-factor, the better the window insulates.

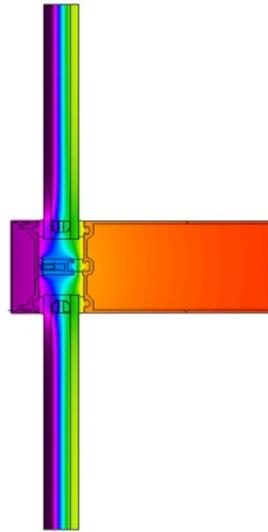

Condensation resistance factor (CRF) measures how well the window resists water buildup. CRF is scored on a scale from 0 to 100. The higher the CRF, the less buildup the window allows.

Performance in Fenestration Systems

Tools for Analyzing Performance

WINDOW: Berkeley Lab WINDOW is a publicly available computer program for calculating total window thermal performance indices (i.e., U-values, solar heat gain coefficients [SHGC], shading coefficients, and visible transmittances [VT]).

THERM (LBNL): Using THERM, you can model two-dimensional heat-transfer effects in building components, such as windows, walls, foundations, roofs, doors, and other products where thermal bridges are of concern.

The U.S. Department of Energy (DOE) Lawrence
Berkeley National Laboratory (LBNL)

The two most common software tools used to simulate fenestration products in North America are WINDOW and THERM.

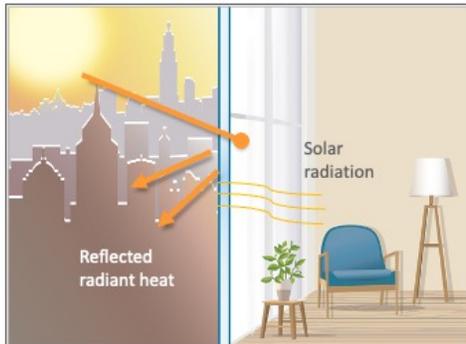

WINDOW allows the simulator to create the glazing system(s) that the fenestration product could incorporate. The glazing systems and unique attributes are then imported into THERM, where the framing system is created and the material properties are assigned. Once all of the framing profiles are simulated (jamb, sill, head, meeting rail, etc.), the THERM file is transferred back to WINDOW, where the entire fenestration assembly is modeled and the total performance of the that product is calculated. The results include U-factor, solar heat gain coefficient (SHGC), visible transmittance (VT), and condensation resistance (CR).

Modeling and simulating software allows designers to see how changes in the profile design, thermal barrier material, and glazing options impact the overall performance of the fenestration system.

Performance in Fenestration Systems

Solar Heat Gain Coefficient (SHGC)

The SHGC is the fraction of incident solar radiation admitted through a window, both directly transmitted and absorbed and subsequently released inward. SHGC is expressed as a number between 0 and 1. The lower a window's SHGC, the less solar heat it transmits.

Solar heat gain can provide (free) heat in the winter but can also lead to overheating in the summer.

© Azon

Sound Control

Sound control for entire fenestration system, rather than for the individual acoustical fenestration components.

Outdoor-indoor transmission class (OITC) is a standard used for indicating the rate of transmission of sound between outdoor and indoor spaces in a structure.

Solar heat gain coefficient (SHGC) measures how well an opening blocks heat from sunlight. The SHGC is the fraction of the heat from the sun that enters through a window expressed as a number between 0 and 1. The lower the SHGC number, the less solar heat is transmitted.

Building codes, along with building owners and architects, are now specifying sound control for the entire fenestration system, rather than for the individual acoustical fenestration components.

Outdoor–indoor transmission class (OITC) is a standard used for indicating the rate of transmission of sound between outdoor and indoor spaces in a structure. Based on the ASTM E-1332: Standard Classification for the Determination of Outdoor-Indoor Transmission Class, OITC utilizes a source noise spectrum that considers frequencies down to 80 Hz (aircraft/rail/truck traffic) and is weighted more to lower frequencies.

Commercial Fenestration and Its Efficiency and Sustainability Possibilities

Aluminum for Buildings Is Sustainable

- Aluminum is 100 percent recyclable and can be repeatedly recycled, retaining the same material physical properties.
- Aluminum is the third most abundant element in the earth's crust next to oxygen and silicon, and the most abundant metal in nature.
- Aluminum is a natural, durable material ideally suited for fenestration products designed to include a thermal barrier to facilitate energy savings.

Aluminum Extruders Council | www.aec.org

Everything manufactured comes from something that was mined from the earth or grown from its soil. As long as industry demands energy, chemicals, and metals, environmental factors are in question.

Why is aluminum for buildings sustainable?

- Aluminum is a noncombustible and natural material.
- It is the third most abundant element in the earth's crust next to oxygen and silicon, and the most abundant metal in nature.
- Aluminum is environmentally friendly and nontoxic, including at high temperatures.

Aluminum Life Cycle: The Never-Ending Story

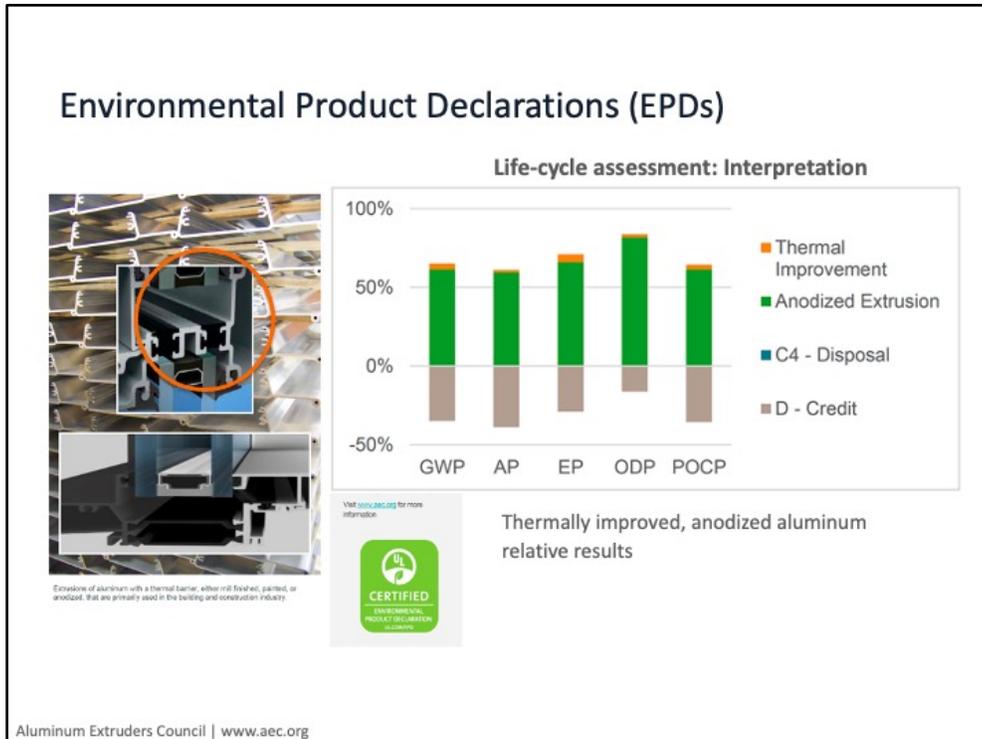

- Aluminum frames are corrosion resistant when anodized and painted, ensuring the sustainability of windows used in most environments.
- Of all materials used for the fabrication of modern windows, aluminum is superior to vinyl, wood, and fiberglass in absolute terms of the life-cycle story.
- Aluminum extrusion environmental product declarations (EPDs) and life-cycle assessment (LCA) quantify the sustainability.

Aluminum Extruders Council | www.aec.org

- Of all the aluminum ever produced, 73 percent is still in use today.
- Annual benefits of aluminum recycling:
 - Approximately 7.5 million tons of solid waste is avoided.
 - About 27 million tons of CO₂ equivalent of greenhouse gas emissions is avoided—equivalent to eliminating five large (1,000 MW) coal-fired power plants.

Environmental Product Declarations (EPDs)

UL Environment was the program operator and verifier of the EPD for thermally improved aluminum extrusion products on behalf of the Aluminum Extruders Council. The results represent the cradle-to-gate and end-of-life environmental performance of thermally improved aluminum extrusions with the three finishing options: mill finished, painted, and anodized, as shown in the EPD.

GWP: Global warming potential

ODP: Ozone-depletion potential; depletion potential of the stratospheric ozone layer

AP: Acidification potential of land and water

EP: Eutrophication potential; from the Greek word "well-nourished," excessive richness of nutrients in a lake or other body of water, frequently due to runoff from the land, which causes a dense growth of plant life and death of animal life from lack of oxygen

POCP: Photochemical ozone creation potential; examples: aromatic and olefinic hydrocarbons showed the highest POCP values, with halocarbons the lowest

Aluminum Framing in Commercial Fenestration

- Building designers look for a variety of attributes in a commercial fenestration system: structural performance, finish and color options, design capability, strength, and the ability to withstand climatic stress.

Aluminum windows are able to provide all of these benefits:

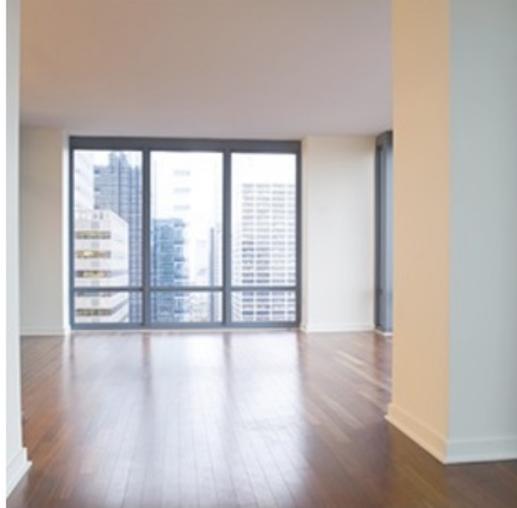

- Excellent structural performance
- Narrow sightlines
- Recycled content
- 100 percent reusability
- Unlimited color finish options
- Contributions to green building program credits
- Catastrophic event protection: hurricane, blast, tornado, intrusion

Aluminum frames also provide increased design flexibility over other framing materials. The thinner frames possible with aluminum make for narrow sightlines, enabling large expanses of glass to be supported with minimal aluminum material.

While maximizing daylighting provides both energy savings and health benefits, the same aluminum that makes large glazed areas possible is also a highly conductive material. The solution to aluminum's conductive properties is to be found with the use of thermal barriers. They eliminate the metal-to-metal bridge that acts as a conductor of hot or cold temperatures through the aluminum frame, replacing it with a very low conductive material so that high thermal performance with expansive glazing is maintained.

Commercial Fenestration and Its Contribution to Occupant Health

Sound Transmission and Health

- Fenestration system components affect outdoor-indoor sound transmission in the exterior wall.
- The Park Central Hotel New York is located in a busy traffic area near Central Park. Glazing includes a warm-edge spacer and polymer thermal barrier in the framing. The combined system is proven to contribute to overall sound-transmission improvements.

One characteristic of optimal window performance is minimized sound transmission. Building codes, owners, and architects are now requiring sound control for the entire fenestration system, rather than for the individual acoustical fenestration components.

Outdoor-indoor transmission class (OITC) is a standard used for indicating the rate of transmission of sound between outdoor and indoor spaces in a structure. Based on the ASTM E1332: Standard Classification for the Determination of Outdoor-Indoor Transmission Class, OITC utilizes a noise spectrum that considers frequencies down to 80 Hz and includes the lower frequencies produced by aircraft as well as rail and truck traffic.

Building Strength and Health

Maximizing window strength is another important consideration. Devoting sufficient attention to the building envelope design and material selection becomes especially important in regions prone to hurricanes, earthquakes, and other catastrophic occurrences. The high shear strength and load resistance of aluminum frames add safety elements to a structure.

Blast Protection

- Improvements to the historical 1960s John F. Kennedy Federal Building in Boston added high security, comfort, energy efficiency, and long-term durability.
- Nearly 5000 original windows—including bent corner units—were replaced with high-performance, energy-efficient, blast-resistant windows.

Maximizing window strength is another important consideration. Devoting sufficient attention to the building envelope design and material selection becomes especially important in regions prone to hurricanes, earthquakes, and other catastrophic occurrences. The high shear strength and load resistance of aluminum frames add safety elements to a structure.

In the fabrication of the frame, the thermal barrier must be able to adhere strongly to the finished substrate. When polyurethane is placed into an aluminum profile that has already been painted or anodized, additional measures must be taken to ensure the frame's strength is maintained. A process that abrades the cavity surface to create hooks holds the thermal barrier securely, mechanically locked in place, and is designed to provide years of reliable performance. The resulting aluminum polymer composite offers undiminished structural integrity over a long service life, even under extreme conditions and temperature changes.

Example: Improvements to the historical 1960s John F. Kennedy Federal Building in Boston added high security, comfort, energy efficiency, and long-term durability.

Nearly 5000 original windows—including bent corner units—were replaced with high-

performance, energy-efficient, blast-resistant windows. The JFK Building windows are intended to survive catastrophic events and protect occupants, and they exceed the industry standards for high shear and tensile strength. The material properties of the aluminum thermal barrier framing with a mechanical lock are ideal for use in government and public buildings where impact or blast hazard is at a high risk.

Daylighting and Health

Maximizing daylighting not only reduces lighting energy needs but also provides health benefits to occupants. Worker productivity, student performance, and hospital patient recovery have all shown improvements in studies of the benefits of daylighting.

Maximizing daylighting not only reduces lighting energy needs but also provides health benefits to occupants. Worker productivity, student performance, and hospital patient recovery have all shown improvements in studies of the benefits of daylighting.

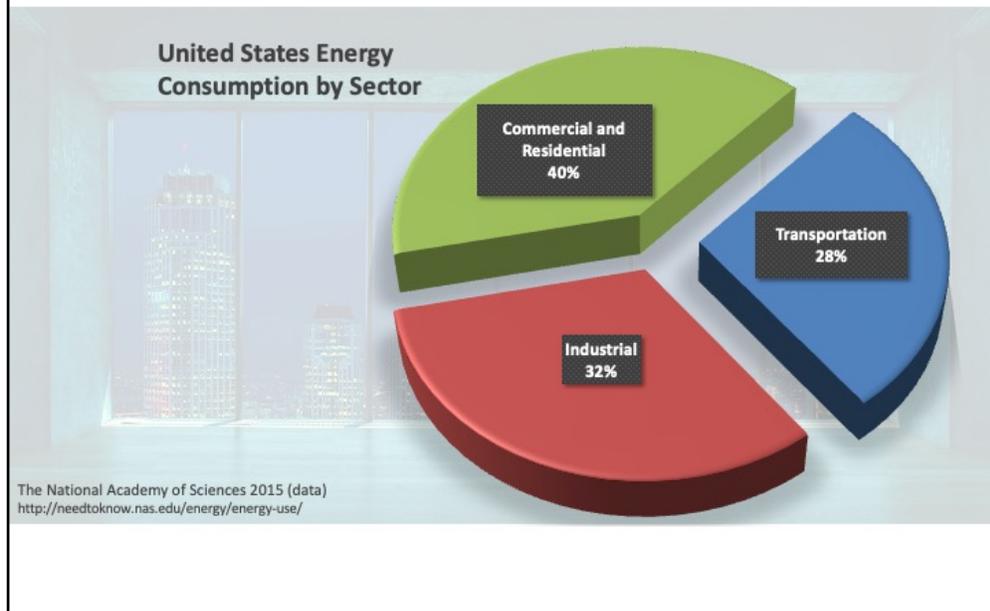

The strength of aluminum allows slim frame profiles to support a higher percentage of glass for improved daylighting and views.

To achieve the best possible daylight transmittance with the least amount of heat gain or loss, window performance is dependent on both the glazing and frame efficiency.

Commercial Fenestration for Energy and Cost savings

Commercial Building Energy Consumption

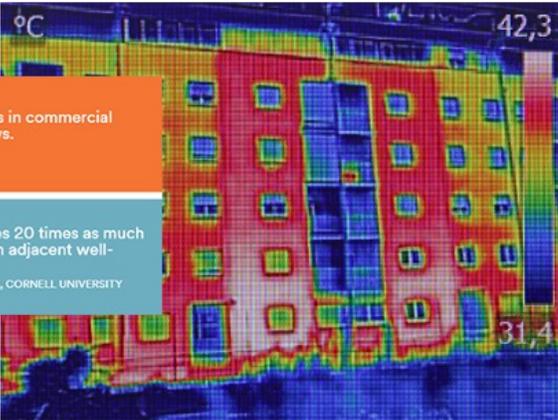

We use energy in homes and commercial buildings in similar ways.

We keep rooms at a comfortable temperature, illuminate our spaces, heat water for bathing and laundry, and depend on computers, copiers, appliances, and other technologies. So perhaps it is not surprising that in 2015, 40 percent of all the energy consumed in the United States went to powering homes and commercial buildings.

Energy Loss in Commercial Buildings

40% Nearly 40% of heating loss in commercial buildings is due to windows.

Commercial Fenestration Performance: Structural Thermal Barriers and High-Performance Glazing

Beginning in the 1950s, single-pane products advanced into insulating glass, slowly replacing the once-popular storm panel applied to a single-glazed window. In these units, the cavity between the two glass panes acts as an insulator, preventing exterior climate conditions (whether hot or cold) from transferring in.

By the 1970s, the use of insulating glass in residential and commercial applications grew in popularity, making significant strides in energy conservation for windows. By replacing aluminum spacers with warm-edge spacers, and filling with inert gases such as argon or krypton, insulating glass units can reduce convection by as much as 10 percent compared to normal air.

Thermal Conductivity

The ability of a material to transmit heat.

The higher the number, the easier it is for heat to transmit.

Conductivity: great for beverages...

The thermal conductivity of aluminum is **1,109**

...poor for buildings

Non-thermal aluminum frame

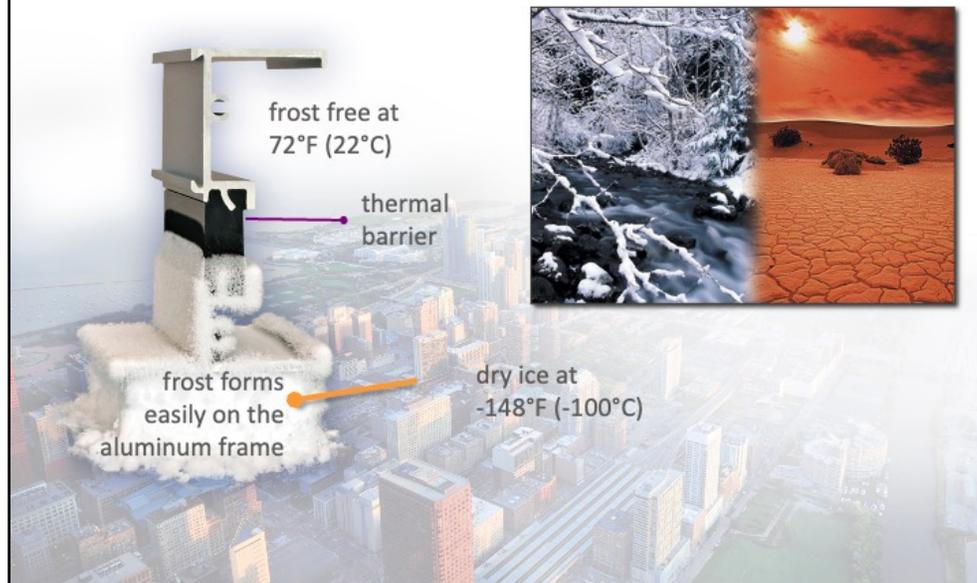

Aluminum is an outstanding material for soda cans; however, it is highly conductive.

Single-pane windows, together with metal-framing materials, offered little or no energy savings, as they were both thermally inefficient and offered paths for climatic conditions to pass, including condensation and frost.

Optimizing window performance must include minimizing heat transfer and condensation while maximizing energy savings.

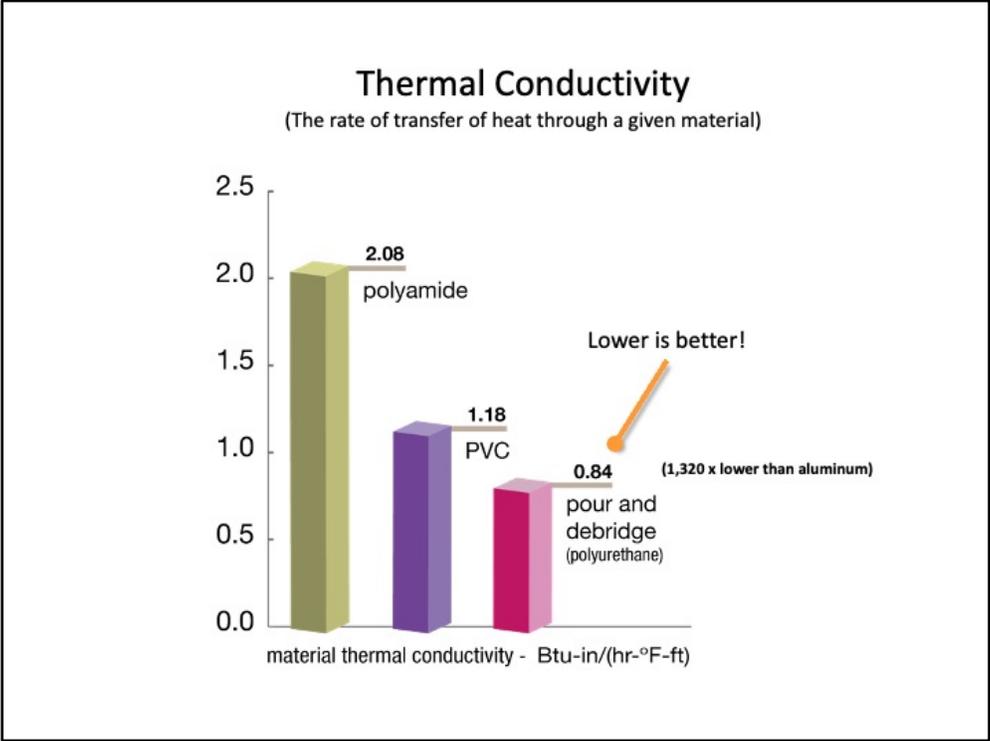

The potential health effects of excessive water vapor with non-thermal windows must also be considered.

Role of Thermal Barriers

When used in a frame, an element of low-conductance material known as a thermal barrier provides aluminum significant thermal performance characteristic.

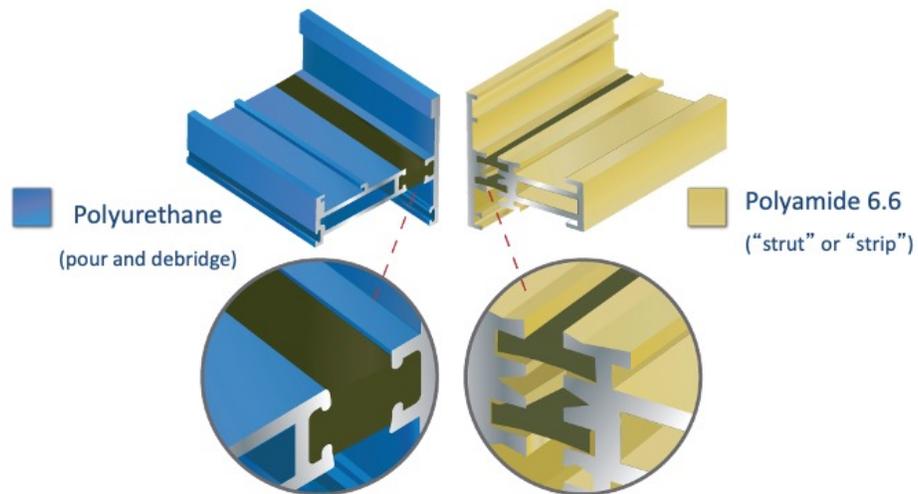

No metal-to-metal contact means the high conductivity of aluminum is no longer an issue. Heat now must pass through the very low conductive polyurethane polymer material, resulting in improved thermal performance of the unit.

Among the attributes demanded by building designers, improving building thermal efficiency for long-term energy conservation typically tops the list. The use of a thermal barrier material within the frame allows aluminum fenestration to provide better thermal performance by lowering the thermal conductive.

Not all insulant material used for the purpose of interrupting heat flow in aluminum perform the same.

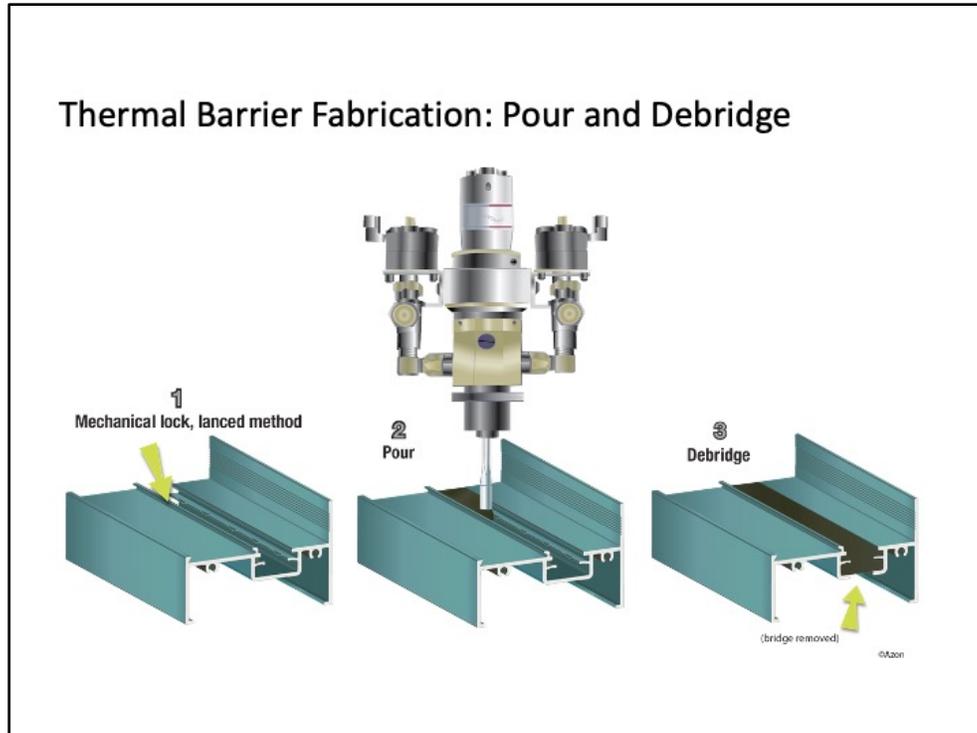

Thermal Barrier Types and Comparisons

The two most common types of thermal barrier for aluminum fenestration products are shown at right. The blue images show a pour and debridge system that uses a polyurethane polymer material.

The yellow images show a strip system, also called a strut system. This type of system incorporates a polyamide material.

Thermal Barrier Fabrication: Pour and Debridge

The pour and debridge system starts with a single aluminum profile. After the profile is finished a mechanical lock is prepared within the fill cavity of the aluminum profile. Next, the cavity is filled with a liquid polyurethane polymer. The polymer then solidifies within the aluminum cavity. Lastly, the bottom part of the aluminum cavity is removed and forms a non-continuous aluminum profile that requires the heat transfer to pass through a very low conductive material, thus improving the thermal performance of the unit.

Mechanical Locks Improve Structural Strength

Method 1

Abrasion hooks improve the adhesion between the polyurethane polymer and the surface of the thermal barrier pocket in the aluminum window extrusion.

Abraded Method

Method 2

Lanced Method

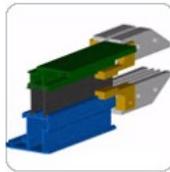

Lanced indentations mechanically lock the thermal barrier polymer in place to ensure maximum adhesion of the thermal barrier to durable architectural finishes.

The structure must remain strong, thus mechanically locking and embedding the polymer to the aluminum results in high shear strength.

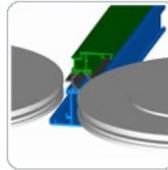

Thermal Barrier Fabrication: Strut (or Strip System)

Knurling. Knurling is the first step in the production process. It is performed to produce teeth in the aluminum pocket that will “bite” into the strut during the crimping process. Proper knurling is required to insure adequate shear strength of the composite profile.

Insertion. Prior to struts being inserted, they are properly selected and verified against the production paperwork.

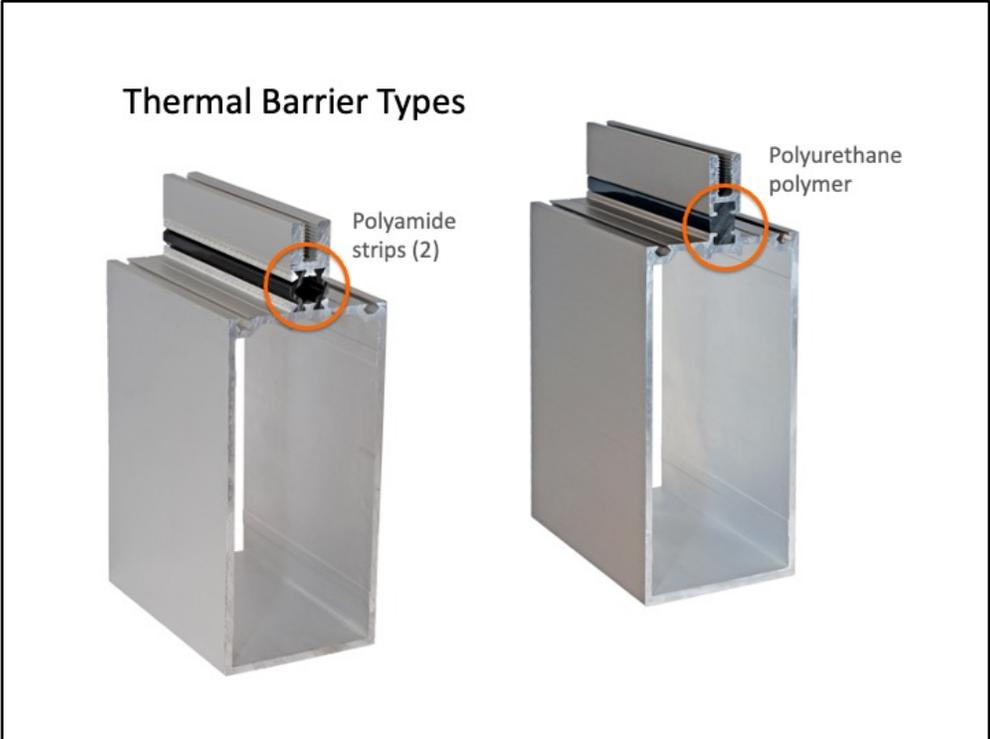

Crimping. The crimping process uses three sets of wheels that rotate the aluminum on to the strut to crimp it into place, forming the bond between the two extrusions and the strut.

The polyamide strip system is composed of two separate aluminum profiles that are connected by the thermal barrier material.

The interior and exterior of the profiles are finished and then run through a knurling machine that puts ridges on the thermal barrier cavity of the aluminum profile.

The polyamide comes to the manufacturer in strips, and these strips are threaded into the cavities of the aluminum profiles.

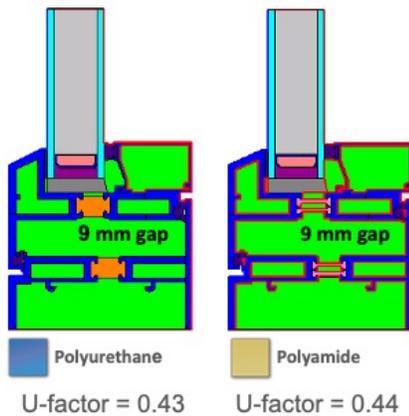

The majority of thermally broken aluminum fenestration extrusions used in commercial buildings contain either polyurethane or polyamide thermal barrier systems because they meet or exceed the thermal and structural specifications of most projects.

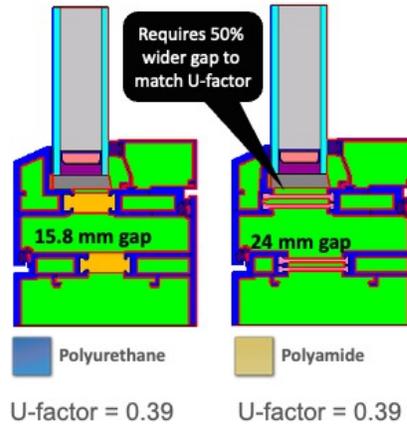

Keys to Thermal Efficiency:

Thermal Conductivity and Separation of the Aluminum

Similar thermal gap:

Same U-factor, dissimilar gap:

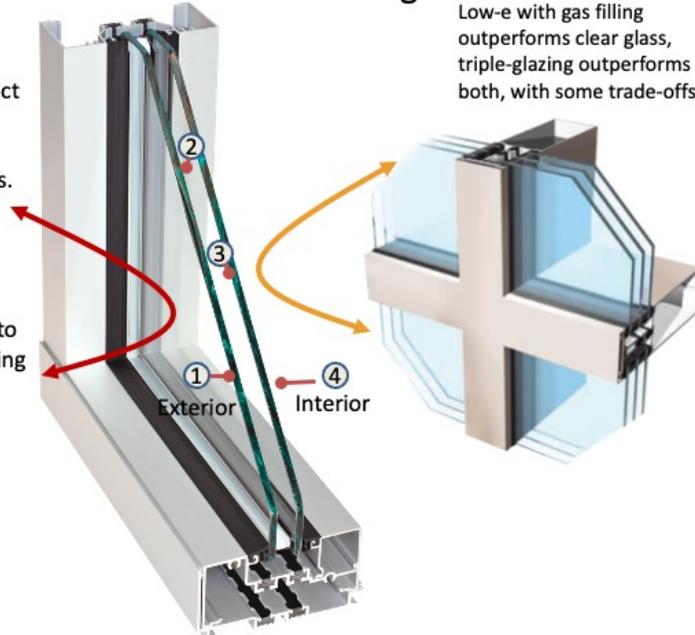

Along with thermal conductivity, the thermal performance can be improved by the “gap” of the thermal barrier or the distance that the heat must flow through the low conductive material. Here you can see how the material with the lower thermal conductivity has superior performance when the gap is the same (9 millimeters) and how the lower conductive material will have the same performance with a smaller gap.

Insulating Glass for Commercial Buildings

Low-e coating on surface ② helps reflect heat to the outside, reducing solar heat gain and cooling costs.

Low-e coating on surface ③ reflects infrared heat back into interior space, reducing heating costs.

Some IGU will have **low-e** on surface ④.

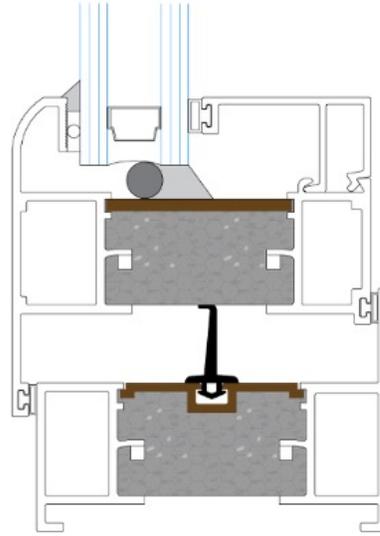

Low-e with gas filling outperforms clear glass, triple-glazing outperforms both, with some trade-offs.

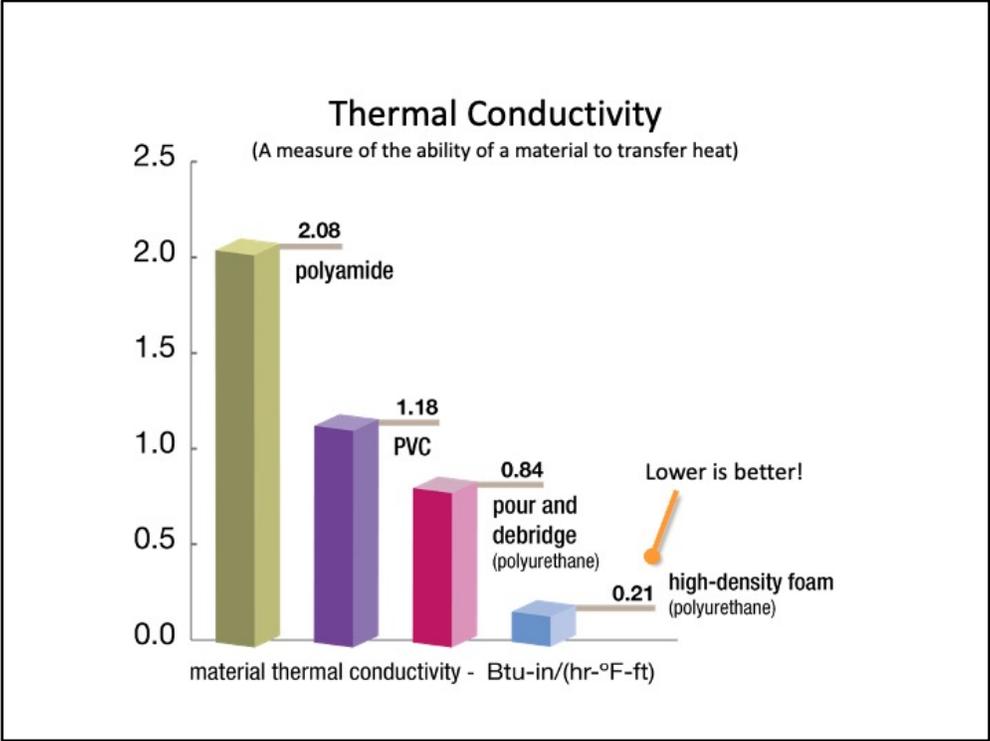

Low-e coatings, warm-edge spacers, and other high-performance glazing materials help offset some of the difference in U-factor and condensation resistance while keeping the SHGC and visible light transmittance high in the insulating glass units.

High-Density Polyurethane Foam

Significant Performance Improvement

- High-density polyurethane foam core for commercial windows and doors
- Major breakthrough in thermal performance for aluminum fenestration products
- Thermal barrier system with the lowest conductivity
- Meeting stringent global energy standards including ENERGY STAR, PassiveHouse, and International Energy Conservation Code (IECC)

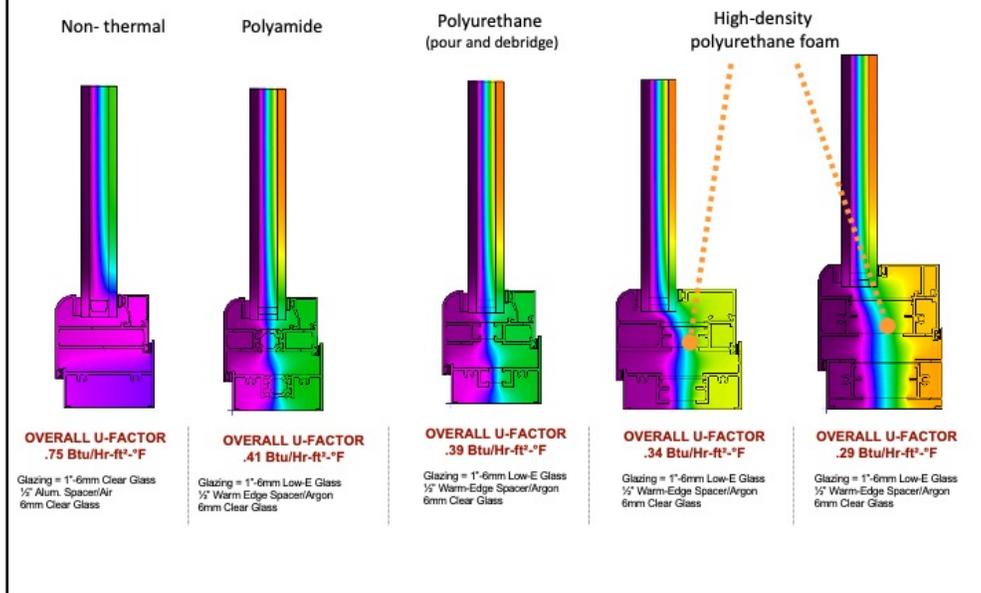

As mentioned earlier, the use of a thermal barrier material within the frame allows aluminum fenestration to provide better thermal performance by lowering thermal conductivity.

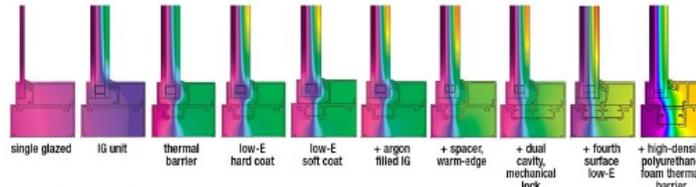

To further interrupt heat flow in aluminum is the introduction of high-density polyurethane foam, the thermal barrier material with the lowest conductivity.

Changes in Commercial Fenestration Performance Over Time

Operable commercial windows thermal performance has increased greatly in the past 10 years, and with new thermal barrier foam technology, the performance is taking another step forward with U-factors below 0.30.

Advances in thermal barriers, glass configuration, and spacers have led to substantial improvement in fenestration performance over time.

By adding warm-edge spacers, inert gases, such as argon or krypton, an insulating glass unit can reduce convection by as much as 10 percent compared to normal air. The air-space improvement will account for a reduction of 0.02–0.03 units in total U-factor.

New Standard in Sustainability

Creative and Innovative Product

High-Density Polyurethane Foam

- After two years of intense research, the largest privately owned provider of fenestration solutions in the United Kingdom develops a high-density polyurethane foam thermal barrier to cope with extreme weather conditions.
- Simple, cost effective, and lowest U-factor
- 100 percent recyclable and has been designed to meet the Passivhaus (Europe) standard.
- Green Guide rating of A for use in commercial projects and a life expectancy in excess of 40 years
- Able to receive double or triple glazing for maximum thermal and acoustic performance

The next step in thermal barrier technology for commercial windows and doors is a high-density foam.

New Standard in Sustainability: Europe

Creative and Innovative Product

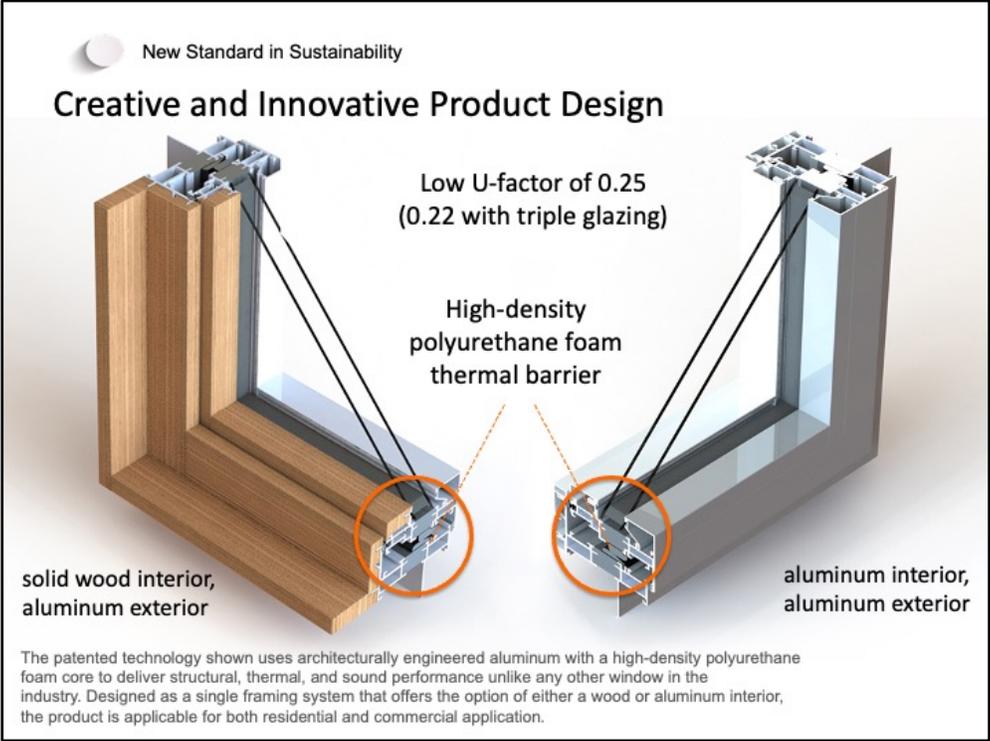

Introduced in 2016 at a major UK Window and Door Expo

Rigorous Passivhaus standard for residential windows in the United Kingdom states:
U-factor must be 0.80 W/m²*K (0.14 Btu*in/h*ft²*F) or below.

- Triple glazed casement = 0.80
- Triple glazed fixed = 0.77

Utilizing high-density polyurethane foam thermal barrier

This commercial aluminum window when triple glazed is the first to meet the Passivhaus requirements in the UK (must be 0.80 ((0.14)) or lower).

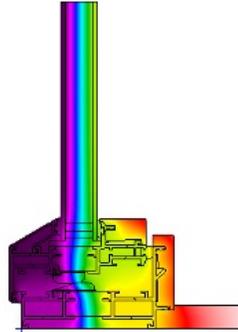

Manufactured in the United States*, the patent-pending series of windows offers both a wood or aluminum interior with a high-density polyurethane foam core.

* An American company founded in 1949

Comparing U-Factor of Casement or Awning Windows

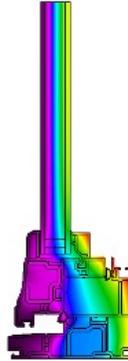

Aluminum-clad wood casement
with polyurethane foam
thermal barrier

Windows Save Empire State Bldg. \$948K

By MEMERIA GORDON

NEW YORK—A 5,460-window retrofit that was completed in June at the Empire State Building here is expected to cut the facility's annual energy costs by at least \$948,000.

The project is the first of three phases during which all the building's windows will be replaced, according to Charles Gaugno, director of operations for the Empire State Building and vice president of property management firm Holmberg-Spear Inc. The entire \$5.2 million project cost was paid from the capital budget and received no utility rebates, he noted.

The new windows are expected to cut the 102-floor, 2.25 million-square-foot office building's annual electricity costs by at least \$848,000, Gaugno told EUN, adding that electricity consumption is

expected to drop by 6,974,311 kilowatt hours a year. In addition, the window replacement is expected to cut costs for steam purchased from local utility Consolidated Edison by about \$103,000 a year, he continued. Fatty steam savings are expected to total 10,764,000 pounds.

The savings estimates represent a 16 percent reduction in energy consumption and costs, Gaugno observed. However, he claimed the projections are conservative and savings could actually approach 25 percent. Based on the most conservative

estimate, payback would be achieved in about six years.

Phase 1 of the retrofit involved installing 5,460 TR-9003 heavy commercial double-hung windows by Traco, Pittsburgh, Pa. The 60-by-48-inch aluminum-frame windows utilize one-inch-thick insulated tempered safety glass, accord-

ing to Dell Grantlund, Traco's special projects manager. The TR-9000 has an R-value of 1.6, while the building's original single-pane windows had an R-value of 1.4. The new windows can also be tilted in to allow them to be washed from inside the building, Grantlund noted.

NEW CONSTRUCTION PROFILE: SCHOOLS District to Use New Bldgs. as Future Models

By REGINA NELSON

SPokane—Three new energy-efficient elementary school buildings completed here in February will be used as templates for future facilities built by Spokane School District 81, Hamblen, Logan, and Stevens Elementary Schools

In the first portion of a three-phase retrofit, workers at New York's Empire State Building replaced over 5,000 windows with energy-efficient models that are expected to provide steam and electricity cost savings amounting to almost \$1 million a year.

PSI Opens Wheeling Tariff to 25 Users

PLAINFIELD, Ind.—PSI Energy here has told 25 large customers they qualify for a transmission tariff that lets them buy power from other suppliers. Rider 19 was created in connection with a contract signed with Novoco Steel in 1990, a spokeswoman said. Each Rider 19 contract must be negotiated individually. It is open to users with at least five megawatts (Mw) of maximum load, at one location. PSI can wheel a total of up to 300 Mw at Rider 19 rates. Minimum contract term is 10 years, with five years' termination notice.

"This would have been a greater act of courage for a more expansive utility," she admitted. PSI has an industrial rate around three cents a kWh. "We're doing this because our largest customers told us they want choice. The utilities who will succeed in a more competitive world will be the ones who are good at serving customers. We have to learn to operate more like a business and Rider 19 will allow us to gain valuable experience in dealing with the day-to-day realities of competition. We think and

PORT FOLK, La.—Thanks to a shared savings deal, Fort Polk Army Base here expects to

The Empire State Building is one of the most recognizable buildings in the world, and a perfect example of the energy savings that can be realized when energy-efficient thermally improved windows are installed.

When the Empire State Building was completed in 1931, it contained steel-framed windows with single-pane glass and offered poor thermal efficiency.

In 1994, the renovation of the building was completed with the installation of 5,460 thermal barrier aluminum windows containing insulating glass. These energy-efficient windows are expected to save the Empire State Building \$948,000 in heating and cooling costs annually, representing a 16–25 percent reduction in energy consumption and costs.

 OITC Rating 36

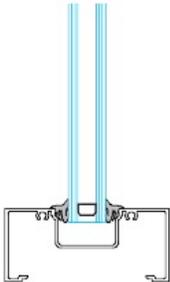

Fenestration system components affect outdoor-indoor sound transmission in the exterior wall.

Sound transmission OITC

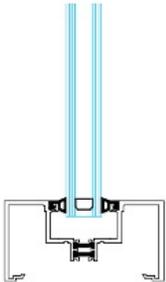

Glazing system components in the Park Central New York (located in a busy traffic area near Central Park) include a warm-edge spacer and polymer thermal barrier in the framing. The combined system is proven to contribute to overall sound-transmission improvements (based on sound transmission OITC).

Storefront: Framing Types

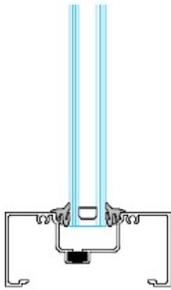

Non-thermal storefront

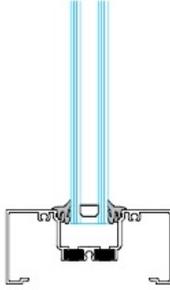

Polyamide thermal barrier storefront

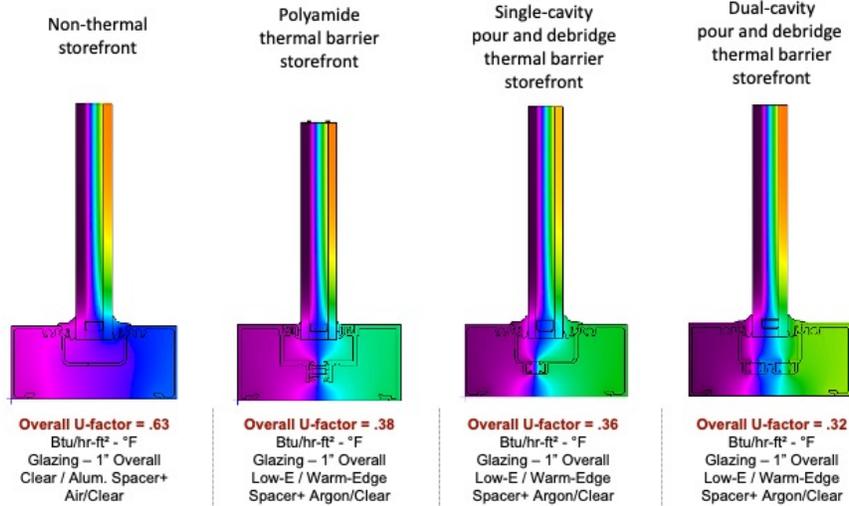

Single-cavity pour and debridge thermal barrier storefront

Dual-cavity pour and debridge thermal barrier storefront

Storefront: Performance Comparison

A dual-glazed storefront's performance can vary greatly depending on the thermal requirements as shown here. The key with storefront is to keep the width at the traditional 4½ inches and the sightlines as small as possible.

Thermal Frame Unit

Curtain Wall

SunShade

Vented Window

In Colorado, state-funded higher-education buildings are required to be designed and built to LEED Gold standard. The new Bioengineering Building qualified for LEED Gold certification.

A highly efficient curtain-wall system, integrated fenestration, and high-performance glazing systems, along with interior and exterior sunshades on the building's south facade, allow for ample daylighting, and all labs and offices have light sensors to decrease electrical usage.

The building's efficient envelope, position on site, and naturally ventilated three-story atrium takes advantage of the Colorado air as it flows west to east.

Passive solar gain low-e to maximize efficiency in cold

First and only LEED Platinum multifamily in Arlington County

- Horizontal sliding and fixed
- Glazing is 1-inch insulated high performance solar control low-e and passive solar gain low-e on south and west exposure
- Mechanical lock, pour and debridge thermal barrier

Contractor: **Clark Builders Group**
Architect: **Bonstra | Haresign**
Glazing: **Advanced Window Inc.**

Arlington County's Green Building Density Bonus Program incentive scheme was established in 1999 and has been consistently updated in step with the ever-evolving standards of LEED.

2019 Best in Green Awards (BIG) Winner

Type: Multifamily Market Rate

Project: [Ten at Clarendon](#)

For more information, please visit the official site of [National Association of Home Builders](#)

In 2016, Arlington County was named the nation's First Platinum-level county under the U.S. Green Building Council's newly created LEED for Communities program.

Note: The project location is less than 4 miles from the USGBC headquarters in Washington, D.C.

In this project located in Vancouver, the windows are actually different heights, changing in size from floor to floor to maximize natural daylight while reducing heat gain. The lowest office level gets the most shading from other buildings so has the biggest windows. The middle floor has a slightly lower floor-to-ceiling height. The windows on the top floor are the smallest and shaded by panels on the cornice, which wraps around the top of the building.
